

What did we learn ?

- Universe cools adiabatically during expansion
- $T(t) = 1.3E10 \text{ K}/t^{1/2}[\text{s}]$
- Particles are in thermodynamical equilibrium
- Annihilation for $kT \ll m c^2$
- Nucleons and Antiparticles annihilate at $1E12 \text{ K}$
- => overabundance of matter over anti-matter
needed by about $3E-8 (h^2 * \omega)$
- proton and neutrons are seeds for nucleosynthesis ($t < 200 \text{ sec}$)
- components with $kT > \text{binding energy}$ are destroyed

Particles at $T(t)=1E12$

Thermodynamical equilibrium -> chemical equilibrium

- protons, neutrons, photons and leptons
- weak interactions couple leptons and protons/neutron

Nucleosynthesis of the Big Bang

- Summary from last week
- Thermodynamical Equilibrium & FreezeOut
- Probing the Universe before Recombination

Source: Weinberg, 2008, in: Cosmology, Chap. 3.1 and 3.2, (and references therein)

Summary: Thermal Evolution of the Universe

- $T \sim 10^{15} \text{ K}, t \sim 10^{-35} \text{ sec}$: Primitives: step of fundamental part.
- $T \sim 10^8 \text{ K}, t \sim 10^{-6} \text{ sec}$: Protons and neutrons form.
- $T \sim 10^{10} \text{ K}, t \sim 3 \text{ min}$: Nucleosynthesis: nuclei form.
- $T \sim 3000 \text{ K}, t \sim 300,000 \text{ years}$: Atoms form.
- $T \sim 10 \text{ K}, t \sim 10^8 \text{ years}$: Galaxies form.
- $T \sim 3 \text{ K}, t \sim 10^{10} \text{ years}$: Today!

13.7 Byrs

Formation of Heavy Elements & NSE

Abundances in NSE (see earlier lesson)

$$X_i = \frac{g_i}{2} X_p^{Z_i} X_n^{A_i - Z_i} A_i^{3/2} \epsilon^{A_i - 1} e^{B_i/k_B T}$$

with $\epsilon \equiv \frac{1}{2} n_N h^3 (2\pi m_N k_B T)^{-3/2}$

$$= 2.96 \times 10^{-11} \left(\frac{a}{10^{-10} a_0} \right)^{-3} \left(\frac{T}{10^{10} \text{K}} \right)^{-3/2} \Omega_B h^2$$

After freeze out

$$\epsilon = 1.46 \times 10^{-12} \left(\frac{T}{10^{10} \text{K}} \right)^{+3/2} \Omega_B h^2 \Rightarrow T_i \simeq \frac{B_i}{k(A_i - 1) |\ln \epsilon|}$$

Evolution of the n/p Ratio

Rem: $kT \ll m(\text{neutron/proton})$

$$E_n - E_p = Q \quad \text{for } n + \nu \rightleftharpoons p + e^-$$

$$E_n - E_e = Q \quad \text{for } n + e^+ \rightleftharpoons p + \bar{\nu}$$

$$E_n + E_e = Q \quad \text{for } n \rightleftharpoons p + e^- + \bar{\nu}$$

$$Q = m_n - m_p = 1.293 \text{ MeV} .$$

Formation Temperature of Elements

Element drops out of equilibrium
if the binding energy is larger than kT .

4He : 3.1E9 (almost all neutrons go into 4He)

2H : 0.75E9 K

3H : 1.4E9K

3He: 1.3E9K

Evolution of the Neutron Concentration

$$\frac{dX_n}{dt} = -\lambda(n \rightarrow p) X_n + \lambda(p \rightarrow n)(1 - X_n)$$

a) Start value for neutron concentration at $T > 3E10$ K statistical equilibrium:

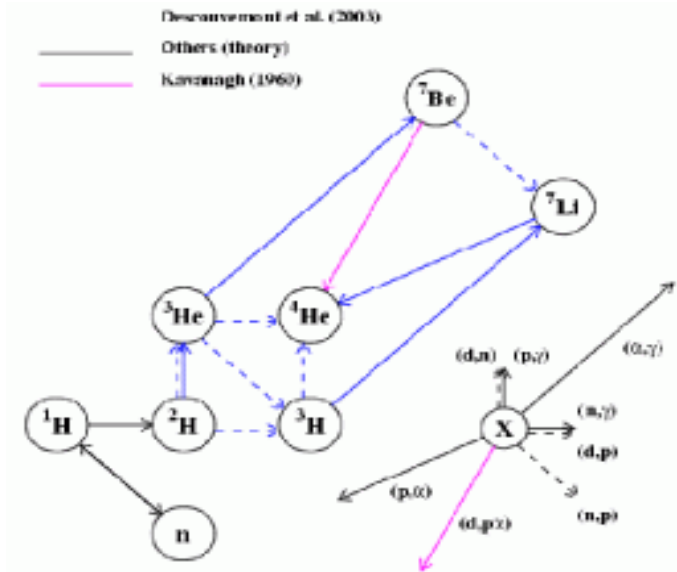

$$\frac{X_n}{X_p} = \frac{X_n}{1 - X_n} = \exp\left(-Q/k_B T\right)$$

b) At about 7E9K (freeze out), electron-positron annihilation stops the equilibrium

- Evolution is governed by neutron decay with a time scale of 886sec

$$X_n \rightarrow 0.1609 \exp\left(\frac{-t}{885.7 \text{ sec}}\right)$$

The BNN Network

Role of the Deuterium Bottleneck for BNN

- Deuterium is d in equilibrium $n+p \leftrightarrow d + \gamma$
- low baryon to photon ratio ($\eta=1E-9$) and low binding energy \Rightarrow low concentration of d
- almost all neutrons go to $4He$ because high binding energy
- temperature too low for heavy elements when D forms
- Fast reactions from D to $7Li$
- No stable isotopes with $Z=5-8 \Rightarrow$ BNN stops at $7Li$

Summary of Big Bang Nucleosynthesis

1: The early universe
 Radiation dominated: $\rho \propto T^4$
 Hubble $H \propto 1/t$
 Big bang nucleosynthesis rate (the only free parameter): $\frac{n}{\sigma} \approx 10^{-8} \approx \frac{1}{\eta} \approx \frac{1}{10^{10}}$

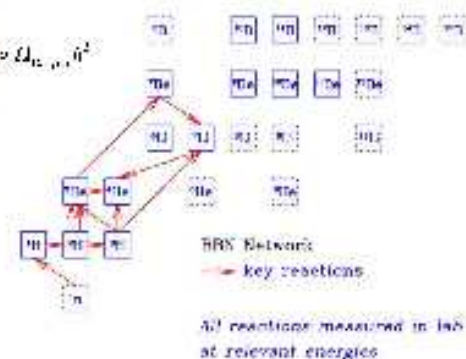

Initial Conditions: $T > 1 \text{ MeV}$, $1 \text{ sec} < t < 100 \text{ sec}$
 n-p weak equilibrium; $\frac{n}{p} \approx \frac{1}{8}$

neutron-decay era: $T \approx 1 \text{ MeV}$, $100 \text{ sec} < t < 1 \text{ min}$
 $\frac{n}{p} \approx \frac{1}{8} e^{-\frac{t}{\tau_n}}$

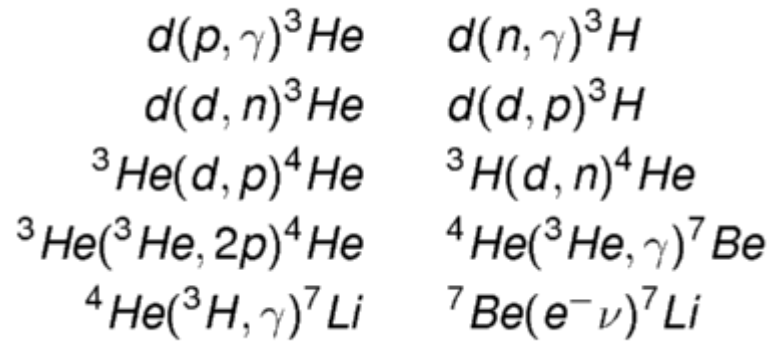

Weak Freezout: $T \approx 1 \text{ MeV}$, $1 \text{ sec} < t < 100 \text{ sec}$
 $\frac{n}{p} \approx \frac{1}{8} e^{-\frac{t}{\tau_n}}$

Deuteron Bottleneck: $T \approx 1 \text{ to } 0.07 \text{ MeV}$
 D created by $n + p \rightarrow d + \gamma$
 but destroyed by high Γ photo-neutrons: $d + \gamma \rightarrow n + p$

Light Elements Form: $T \approx 0.07 \text{ MeV}$, $t \approx 3 \text{ min}$
 essentially all n are consumed \Rightarrow $\frac{n}{p} \approx 24\%$ by mass
 also traces of 2He ($t \approx 1 \text{ s}$)

The BNN Network

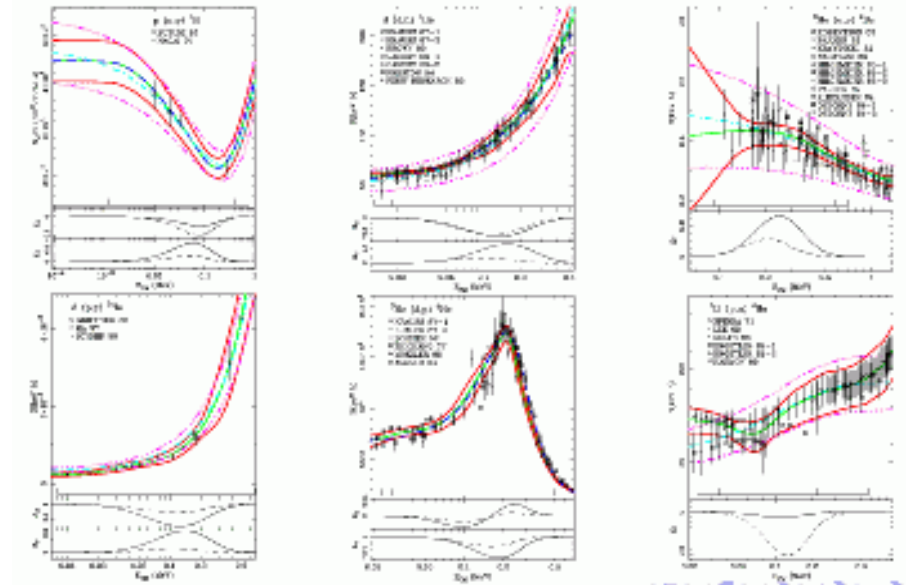

Abundances and Neutrino Flavors

Uncertainty: Neutron half life

Accuracy of the Nuclear Rates

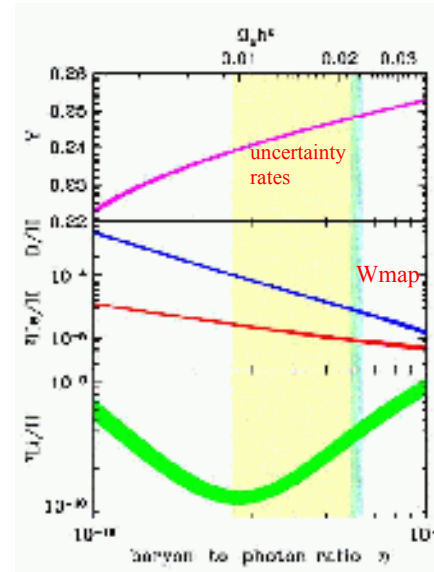

Big Open Questions for the Future: Baryon Asymmetry Sakharov's Conditions (1967):

- baryon number violation (GUT)
- C and CP violation
- non-equilibrium conditions

Rem: parity violation in weak reactions
CP violation observed in neutral kaons
nec requires slow coupling compared to expansion at early phase ($T > 1E12K$)
